Secure tenure rights and control over land for women and men farmers are key to boosting smallholder productivity, rural development and food security. However, in many parts of the world, men and women have inadequate access to secure property rights over land. Women are particularly disadvantaged: even though they constitute on average 43 percent of the agricultural labour force in developing countries, women's ownership of agricultural land remains significantly lower than that of men. Women's lack of secure rights over land translates into lower productivity, perpetrating food insecurity, malnutrition and poverty.

Land statistics disaggregated by sex are essential to monitor progress towards a more secure and gender-equitable land tenure system and to highlight the disparities in land rights between women and men, providing a sense of women's economic empowerment in agriculture. While clarifying some of the concepts on land, this paper also provides an overview of five indicators of the Gender Land and Rights Database (GLRD), the dimensions they capture and how each one of them is calculated.

Making sense of gender, land and statistics

Reliable statistics on women's ownership and management of agricultural land are key for improving policy formulations and monitoring the progress towards gender equality in agriculture. Unfortunately, land statistics have often been inaccurate due to the incorrect use of the concepts such as agricultural holder and landowner, often considered as synonyms. While both are important components of land rights, they are different and should not be confused. On the one hand, agricultural holders are the managers of the holding although they may not be the legal owners of the land. On the other hand, landowners are the legal owners of the land and, typically, have the rights to sell, bequeath, or lease it.

When addressing gender inequalities in secure rights over land, it is important to stress the distinction between agricultural holders and landowners. Indeed, women may cultivate and manage parcels but they may not be the owners and therefore, they may not have the rights (or incentives) to make productivity-enhancing improvements. Also, women may be the legal owners of land but they may not have access to it or may not be able to make decisions related to the use of the land because of culture, norms and lack of empowerment.
Towards more accurate land statistics: the GLRD

In order to take into account gender disparities in land rights across countries and monitor progress towards gender-equitable land tenure globally, it is essential to elaborate a harmonized framework for producing and interpreting sex disaggregated data on land ownership and management. To this purpose, in 2014, FAO started a collaboration with IFPRI-PIM programme to develop a common framework for producing sex-disaggregated indicators for FAO’s Gender and Land Rights Database (GLRD). The framework includes five sex-disaggregated indicators:

- **Indicator 1: Distribution of agricultural holders by sex**
- **Indicator 2: Distribution of agricultural landowners by sex**
- **Indicator 3: Incidence of female and male agricultural landowners**
- **Indicator 4: Distribution of agricultural land area owned by sex**
- **Indicator 5: Distribution of agricultural land value owned by sex**

**Indicator 1: Distribution of agricultural holders by sex**

Indicator 1 measures the percentage of female and male agricultural holders out of the total population of agricultural holders (Figure 1). The indicator focuses on primary managers of agricultural holdings, with the understanding that holders may or may not be legal owners of the holding. This indicator is available for a great number of countries because information on agricultural holders is collected through national agricultural censuses. However, since this indicator considers the management of the agricultural holding as a whole, it does not capture the presence of men and women who separately own or manage few plots within the holding. Therefore, it is essential to complement the agricultural censuses data with intra-holding level information on the different rights and responsibilities of women and men over agricultural holding. This highlights the need for elaborating separate indicators to capture the different rights and responsibilities of women and men over farm land.

From the results in Figure 1 and Table 1, gender inequalities are evident, but the gender gap appears narrower when examining ownership (Indicator 2) rather than management of holdings (Indicator 1). This highlights the importance of using different indicators to understand land statistics.

Indicator 3: Incidence of female landowners

Indicator 3 adds further nuance to the sex disaggregated statistics on land by showing the share of women out of all women in the country and the share of men out of all men in the country who own agricultural land. This is the incidence of female and male landowners. Where data are available, the indicator also distinguishes whether women and men own the land alone or jointly with someone else.

Graph 1 and 2 show the incidence of male and female landowners for selected countries from the GLRD. Data differ widely by country and depend on whether joint or sole only ownership is considered. Indeed, the gap between male and female landowners appears larger when considering female sole owners and male sole owners than when joint ownership is considered.

For instance, in Zimbabwe, 36% of all women and 36% of all men own land either solely or jointly with another family member. However, only 11% of women compared to 22% of men are sole landowners suggesting that when women own land they are more likely to share the ownership rights with another family member rather than being the sole holders of those rights.
Indicator 4: Distribution of agricultural land area owned by sex

Indicator 4 measures the distribution of agricultural land by sex, that is how much land women and men actually own. While the indicator does not tell us how many men and how many women own land, it does provide a good measure of how the land area is distributed between men and women showing that women’s plots are often significantly smaller than men’s plots. Thus, the indicator reveals significant gender-based differences in the amount of land owned by men and women (Table 2), which should be taken into account when addressing gender inequalities in access to land. This indicator also provides information on how much of the land is owned individually by men and by women and how much is owned jointly. These patterns vary widely across countries.

### Table 2. The distribution of land area and land value by sex: In all nine countries available from Sub-Saharan Africa and Asia, men own a larger proportion of the land area than women. The patterns of individual versus joint ownership differ by country. In the two Asian countries for which joint ownership is reported, it is a small proportion of total household agricultural land.

Indicator 5: Distribution of agricultural land value owned by sex

Indicator 5 attempts to capture differences in the quality of land that women and men own. It measures the share of land value (often self-reported land value) owned by women and the share of land value owned by men, and wherever possible, the share of land value owned jointly by men and women (often couples). Evidence shows that in addition to owning smaller plots, women also own plots of lower quality. The proportions of land value owned by women range from 5% in Niger to 39% in Malawi, while the proportions owned by men range from 34% in Uganda to 78% in Nigeria (Table 2). In general, the proportion of land value owned solely by women is lower than the proportion owned solely by men.

The way forward

The GLRD indicators are constantly updated based on existing data from agricultural censuses, household and agricultural surveys. By mid-2016, land ownership and management information from at least 15 more surveys will be provided through the GLRD. Gendered land statistics from different years will also be included, to allow a better assessment of the progress made towards more secure land rights for both men and women. The aim of the Gender, Land and Right database is to serve as a hub of information for policy makers and advocates of women’s land rights to promote gender-equitable land tenure.
